- Bayesian inference

## Factors?

Markov networks:

$$\mathbb{P}(X_1 = x_1, \dots, X_n = x_n) = \frac{\text{Weight}(x)}{\sum_{x'} \text{Weight}(x')}$$

$$\text{Weight}(x) = \prod_{j=1}^m f_j(x)$$

What are these factors  $f_j$ 's and how does one construct them?

- Hard constraints (CSPs):  $f(x_1, x_2) = [x_1 \neq x_2]$
- Soft preferences (weighted CSPs, Markov networks):  
 $f(x_1, x_2) = \{(\mathbf{R}, \mathbf{R}) : 1, (\mathbf{R}, \mathbf{B}) : 10, (\mathbf{B}, \mathbf{R}) : 10, (\mathbf{B}, \mathbf{B}) : 1\}$

Can we find a more natural/interpretable way to create factors...

Generative story: describe how the world works...

## Generative story

Once upon a time, there was a girl who lived at  $(0, 0)$ .

One day, she wanted to go visit her grandma's house at  $(10, 10)$ .

At every moment, she just chose a random direction that got her closer.

Once he reached her grandma's house, she stayed there and lived happily ever after.

## Generative process

**Generative process:** Going to grandma's

$X_1 = (0, 0)$

for each time step  $t = 2, \dots, T$ :

Generate position  $X_t \sim p(X_t | X_{t-1})$

Factors:

- $p(x_t | x_{t-1})$ : uniform distribution over  $x_t$  which are (i) at most distance one away from  $x_{t-1}$  and (ii) at least as close to the goal

Example:

$$p((0, 0) | (0, 0)) = p((1, 0) | (0, 0)) = p((0, 1) | (0, 0)) = \frac{1}{3}$$

## Running the generative process

Run

Generative model defines a distribution over complete paths.

## Notational aside

"is proportional to":

- $p(x) \propto w(x) \Leftrightarrow p(x) = \frac{w(x)}{\sum_{x'} w(x')}$
- **Example:**  $p(x, y) \propto [x < y]$  places uniform distribution over pairs  $(x, y)$  such that  $x < y$

"is drawn/sampled/generated from":

- $X \sim f(X) \Leftrightarrow \mathbb{P}(X = x) = f(x)$

## Markov models

Notes

**Generative process:** Going to grandma's  
 $X_1 = (0, 0)$   
 for each time step  $t = 2, \dots, T$ :  
 Generate position  $X_t \sim p(X_t | X_{t-1})$

Bayesian network representation:

Variables are nodes, add directed edge to each variable from variables it depends on.

## Factor graph representation

**Generative process:** Going to grandma's  
 $X_1 = (0, 0)$   
 for each time step  $t = 2, \dots, T$ :  
 Generate position  $X_t \sim p(X_t | X_{t-1})$

Weight of assignment is product of factors:

$$\text{Weight}(x) = \prod_{t=1}^T p(x_t | x_{t-1})$$

## Factor graph representation

$$\mathbb{P}(X = x) = \frac{\text{Weight}(x)}{\sum_{x'} \text{Weight}(x')} \quad \text{Weight}(x) = \prod_{t=1}^T p(x_t | x_{t-1})$$

What is the normalization constant? Do variable elimination:

$$f_4(x_4) = \sum_{x_5} p(x_5 | x_4) = 1$$

$$f_3(x_3) = \sum_{x_4} p(x_4 | x_3) f_4(x_4) = 1$$

...

**Important: normalization constant**  $\sum_{x'} \text{Weight}(x') = 1$

$$\mathbb{P}(X = x) = \text{Weight}(x) = \prod_{t=1}^T p(x_t | x_{t-1})$$

This holds for all generative models.

## Generative models summary

Described by a **generative process** (randomized program):  
 convenient representation for **modeling**

Example: **Generative process:** Going to grandma's  
 $X_1 = (0, 0)$   
 for each time step  $t = 2, \dots, T$ :  
 Generate position  $X_t \sim p(X_t | X_{t-1})$

Defines a **Bayesian network** (directed graphical model):

Example:  $X_1 \rightarrow X_2 \rightarrow X_3 \rightarrow X_4 \rightarrow X_5$

Defines a **Markov network** (undirected graphical model / factor graph): convenient representation for **inference**

Example:  $\mathbb{P}(X = x) = \text{Weight}(x) = \prod_{t=1}^T p(x_t | x_{t-1})$

## Outline

- Bayesian networks, factors, Markov networks
- **Applications / examples of Bayesian networks**
- Bayesian inference

**General approach:** model the world via a set of variables and how they were generated (don't solve the problem directly)...

## Application: language modeling

**Generative process:  $n$ -gram model**

For each word position  $t = 1, 2, \dots, T$ :

Generate word  $X_t \sim p(X_t | X_{t-n+1:t-1})$

**Bigram model:**  $(X_1 \rightarrow X_2 \rightarrow X_3 \rightarrow X_4 \rightarrow X_5)$

$$\mathbb{P}(X = x) = \prod_{t=1}^T p(x_t | x_{t-n+1:t-1}): \text{fluency of sentence } x.$$

**Applications:**

- Generate random stories
- Machine translation: make sure output looks like English
- Speech recognition: "I recognize speech" versus "I wreck a nice beach"

## Application: reasoning under uncertainty

**Question:** At the office, you get a call from your neighbor John. What's the probability that there was a burglary?

**$L$ :** location

**$B$ :** burglary happened?

**$E$ :** there was an earthquake?

**$A$ :** alarm went off?

**$J$ :** John called?

**$M$ :** Mary called?

$$\mathbb{P}(L = l, B = b, E = e, A = a, J = j, M = m) = p(l)p(b | l)p(e | l)p(a | b, e)p(j | a)p(m | a)$$

[Demo of simplified network]

- Allows principled incorporation of diverse long-range evidence
- Account for natural reasoning patterns such as explaining away

## Application: document classification

**Question:** given a text document, what is it about?

**Generative process: Naive Bayes**

Generate the document category  $Y \sim p(Y)$

For each word index  $i = 1, \dots, L$ :

Generate word  $X_i \sim p(X_i | Y)$

## Application: medical diagnostics

**Question:** If patient has a cough and fever, what disease(s) does he/she have?

**Generative process: Diseases and symptoms**

For each disease  $i = 1, \dots, m$ :

Generate whether patient has that disease  $X_i \sim p(X_i)$

For each symptom  $j = 1, \dots, n$ :

Generate whether patient has that symptom  $Y_j \sim p(Y_j | X_{1:m})$

## Application: social network analysis

**Question:** Given a social network (graph over  $n$  people), what types of people are there?

### Generative process: Stochastic block model

For each person  $i = 1, \dots, n$ :

Generate the type of that person  $X_i \sim p(X_i)$

For each pair of people  $i \neq j$ :

Generate whether  $i$  and  $j$  are linked  $E_{ij} \sim p(E_{ij} | X_i, X_j)$

## Application: object tracking

### Generative process: Hidden Markov model

For each time step  $t = 1, \dots, T$ :

Generate object location  $X_t \sim p(X_t | X_{t-1})$

Generate sensor reading  $E_t \sim p(E_t | X_t)$

### Other applications:

- Computational biology: gene finding
- Natural language: speech recognition, information extraction

## Application: tracking multiple objects

### Generative process: Dynamic Bayesian network

For each time step  $t = 1, \dots, T$ :

For each object  $o \in \{a, b\}$ :

Generate location  $G_t^o \sim p(G_t^o | G_{t-1}^o)$

Generate sensor reading  $E_t^o \sim p(E_t^o | G_t^o)$

## Outline

- Bayesian networks, factors, Markov networks
- Applications / examples of Bayesian networks
- **Bayesian inference**

## General framework: Bayesian networks

Notes

- Coined by Judea Pearl in 1985, popularized probability in AI
- Variables  $X_1, \dots, X_n$
- For each variable  $X_i$ , have a local conditional probability distribution  $p(x_i | x_{\text{Parents}(i)})$ :

$$\mathbb{P}(X = x) = \prod_{i=1}^n p(x_i | x_{\text{Parents}(i)})$$

## Bayesian inference

Generative models so far have two types of variables:

$X$ : hidden variables describing the world (e.g., actual positions)

$E$ : variables you observe about the world (e.g., sensor readings)

**General approach:** Define a generative process over both hidden and observed variables ("how the observed values came to be").

$$\mathbb{P}(X = x, E = e) = p_{\text{prior}}(x) \cdot p_{\text{likelihood}}(e | x)$$

**Objective:** compute **posterior**  $\mathbb{P}(X_i = x_i | E = e)$  for some query variable  $X_i \subset X$ ?

## Bayesian inference

**Objective:** compute is the **posterior**  $\mathbb{P}(X_i = x_i \mid E = e)$ ?

**Algorithm:**

- Condition on  $E = e$  and produce a factor graph.
- Run inference algorithm (sum variable elimination, Gibbs sampling, or particle filtering).

## Summary

- **Markov networks:** factors specify **local** dependencies, **Weight(x)** induces **global** dependencies (analogy with rewards and utilities); normalize to get  $\mathbb{P}(x = x)$ .
- **Inference algorithm:** compute distribution over query variables taking into account all global dependencies
- **Bayesian networks / generative processes:** randomized program that assigns values to variables (think of a story of how the observed variables got there via hidden dynamics in the world); defines factor graph where factors are local probability distributions
- **Bayesian inference:** observe  $E = e$ , play detective to get  $\mathbb{P}(X = x \mid E = e)$
